## **Tunneling vs. Gcom Data Tunneling**

To most people, *tunneling over TCP* means transporting a particular protocol from one side of an IP network to the other using a TCP connection as the transport mechanism. It is the protocol that is tunneled. What emerges from the far end of the tunnel is a set of protocol objects that look just like the ones that entered the near end of the tunnel. That means the protocol that exits the tunnel must be the same protocol that enters the tunnel.

Gcom's *data tunneling* is quite different: The a Gcom Protocol Appliance 2G (GPA 2G) tunnels only the payload data carried by the legacy protocol. It does so by:

- Terminating the legacy protocol (SNA, X.25, Bisync, etc.)
- Applying a delimiter (header or header/trailer combination) to preserve logical message boundaries needed to send payload data over a byte stream connection such as TCP

The means you can use Gcom's Data Tunneling protocol to convert between legacy protocols on one side of the connection and payload data sent over TCP/IP on the other side.

For example: You can easily feed legacy protocol payload data into...

- Existing TCP/IP devices, such as ATMs, that use simple message-boundary-preserving encapsulations.
- Existing TCP/IP-based applications, such as EDI, that use similarly simple encapsulations.

An added bonus: By connecting a pair of encapsulated TCP connections back to back, you can even achieve protocol translation between any two legacy protocols. For example: If one legacy device talks SNA but another can only supply data via X.25, you can use Gcom's Data Tunneling protocol as a bridge between the two.

## Gcom Data Tunneling Overview

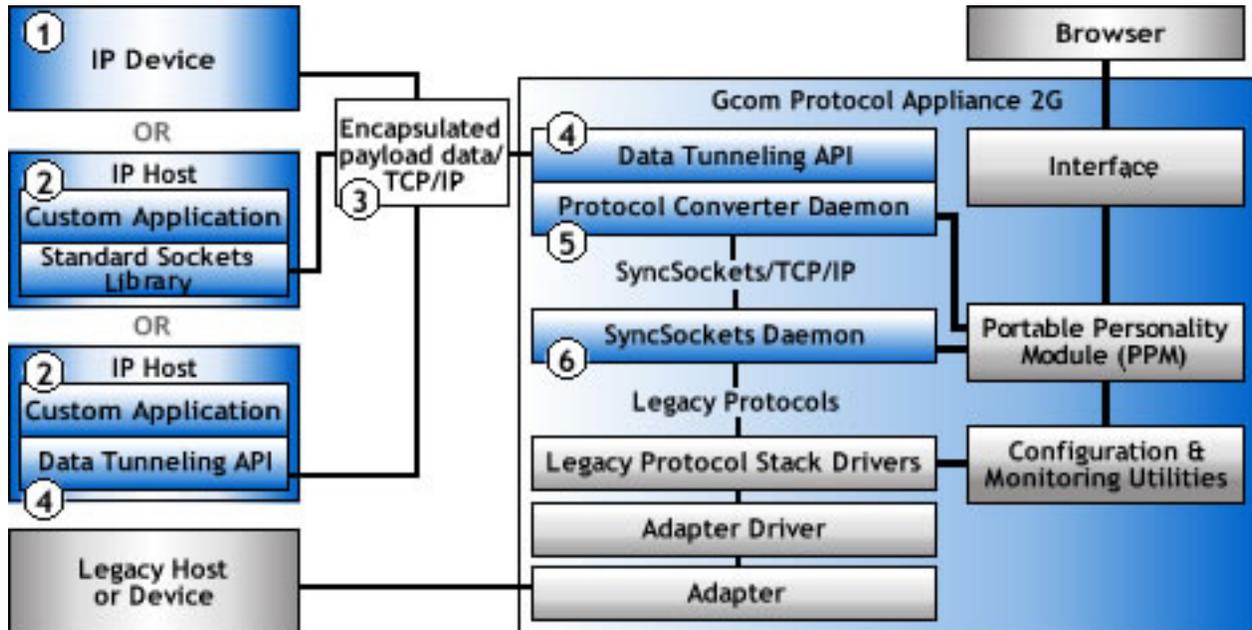

Figure 1 – Gcom Data Tunneling Overview

1. **IP Device** = Device, such as an ATM, TN3270 client, custom equipment, etc., that processes encapsulated payload data and communicates using TCP/IP
2. **Custom Application** = User-developed application that processes encapsulated payload data and communicates using TCP/IP
3. **Encapsulated Payload Data** = Payload data with delimiters added to preserve logical message boundaries needed to send payload data over a byte stream connection such as TCP
4. **Data Tunneling (DT) API** = Gcom® proprietary library of functions (provided in both C and Java):
  - o Used by a developer to create a custom application
  - o Used by a Gcom Protocol Appliance 2G (GPA 2G) to interface with an IP device or a custom application on an IP host
  - o Built on a standard sockets library (an industry-standard repository of C functions to create and use IP communications) to give it a TCP/IP-based look and feel
  - o Offers a wide variety of payload data delimiter formats called *encapsulations*
5. **Protocol Converter Daemon** = Gcom-proprietary, stand-alone application-level program that converts legacy protocol data streams from Gcom's SyncSockets® protocol to encapsulated payload data over TCP/IP

- 6. SyncSockets Daemon** = Gcom-proprietary, stand-alone application-level program that converts legacy protocols to/from SyncSockets protocol over TCP/IP
- 7. Gcom Protocol Appliance 2G (GPA 2G)** = Secure, closed, high-MTBF, small-footprint unit that can convert between legacy protocols on one side of a connection and encapsulated payload sent over TCP/IP on the other side

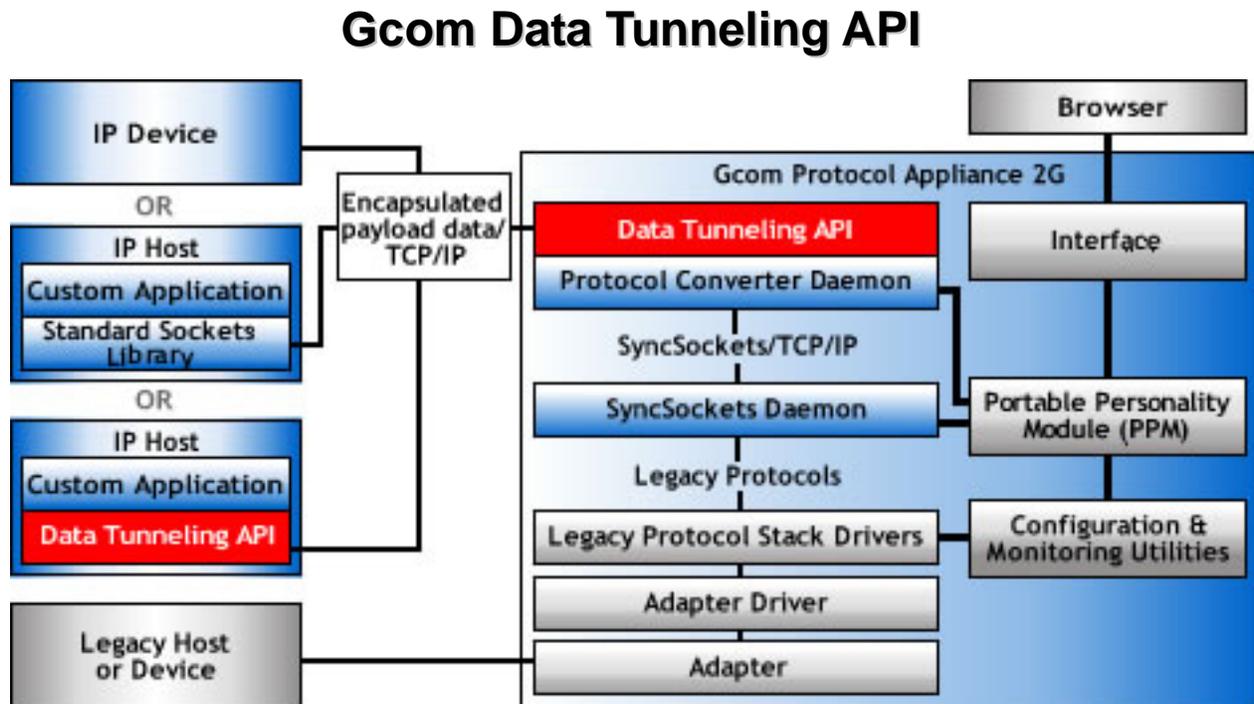

Figure 2 – Gcom Data Tunneling API

The Data Tunneling (DT) API is a Gcom-proprietary library of functions (provided in both C and Java):

- Used by a developer to create a custom application
- Used by a GPA 2G to interface with an IP device or a custom application on an IP host
- Built on a standard sockets library (an industry-standard repository of C functions to create and use IP communications) to give it a TCP/IP-based look and feel
- Offers a wide variety of payload data delimiter formats called *encapsulations*

Gcom's Data Tunneling API advantages:

- Using the Gcom Data Tunneling API to manage TCP connections in either client mode (outgoing connections) or server mode (incoming connections) is easier than using the standard sockets library.
- The Gcom Data Tunneling API has over a dozen built-in data encapsulation techniques that take care of all encapsulation details.
- You can use simple send and receive functions to operate on the payload data.

## API Style

Gcom's Data Tunneling API uses:

- A simple subroutine calling style of interaction with the custom application
- A callback routine to the custom application to signal connection establishment

## **Thread Compatibility**

Gcom's Data Tunneling API routines are all thread-safe and thread-efficient. You can handle connections using threads, poll lists, or any combination of the two that make sense in the context of solving the communication problem at hand.

## **Non-blocking Operation**

By default, Gcom's Data Tunneling API assumes:

- The sockets used for data tunneling are operated in non-blocking mode. This means they must be used in conjunction with `poll` to assure they are readable or writeable when those operations are attempted.
- The custom application uses either threads or poll lists to discover when a socket has data to be read. When the custom application calls the `dt_recv` function, the function returns one encapsulated message with the encapsulation header/trailer removed. If the entire message is not received, the function returns `-1` with `errno` set to `EAGAIN` to read the socket again in order to receive the remainder of the message.
- The custom application uses either threads or poll lists to take care of flow control back pressure when writing to a socket. When the custom application calls the `dt_send` function, the function sends the encapsulated data unless TCP flow control does not permit transmission. A call to the `dt_send` function following a `poll`, which indicates the socket is write ready, should always succeed.

## Data Tunneling API Functions

| API Function                    | Description   |
|---------------------------------|---|
| <a href="#">dt_close</a>        | Close a socket.   |
| <a href="#">dt_init</a>         | Initialize the API and set logging options.   |
| <a href="#">dt_lock_print</a>   | Get the API's log printing mutex.   |
| <a href="#">dt_open</a>         | Open a socket and: <ul style="list-style-type: none"> <li>• Connect to a remote peer.</li> <li>• Or listen for incoming connections from remote peers.</li> </ul> |
| <a href="#">dt_printf</a>       | Print into the log file.  |
| <a href="#">dt_recv</a>         | Receive an encapsulated message from an open socket.  |
| <a href="#">dt_reuseaddr</a>    | Set SO_REUSEADDR option on a socket. (Useful only for listening sockets.)   |
| <a href="#">dt_send</a>         | Send an encapsulated message on an open socket.   |
| <a href="#">dt_set_log_size</a> | Set the maximum size of the log file.   |
| <a href="#">dt_shutdown</a>     | De-initialize the API.  |
| <a href="#">dt_unlock_print</a> | Release the API's log printing mutex.   |

**Table 1 – Data Tunneling API Functions**

### dt\_close

#### Prototype

```
int dt_close(int fd)
```

#### Parameters

| Parameter | Description                               |
|-----------|---|
| fd        | File descriptor for the socket connection |

**Table 2 – dt\_close Parameters**

#### Description

The `dt_close` function closes a socket connection. The passed file descriptor can be the descriptor for a data connection or for a listening socket, as returned by the [dt\\_open](#) function in host mode.

In the case of a:

- Data connection – The connection ceases to exist and data in transit may be lost.
- Listening socket – The listen ceases and the listening thread terminates.

**Return Values**

dt\_close always returns 0.

**dt\_init****Prototype**

```
int dt_init(int log_optns, char *log_name)
```

**Parameters**

| Parameter          | Description   |  |
|--------------------|---|--|
| log_optns          | Logical OR of the following mnemonic options:   |  |
|                    | <b>Options</b>  | <b>Description</b>   |
|                    | DT_LO_ERRORS  | Print errors from failed system calls, allocation failures, etc. |
|                    | DT_LO_CODE_PATH   | Print details of the execution path through the API code         |
|                    | DT_LO_WARNINGS  | Print warnings about inconsistent data structures                |
|                    | DT_LO_DATA  | Print the data portion of sent and received messages             |
|                    | DT_LO_DEBUG_LEVEL1  | Verbose debugging  |
|                    | DT_LO_DEBUG_LEVEL2  | More verbose debugging   |
| DT_LO_DEBUG_LEVEL3 | Even more verbose debugging   |  |
| log_name           | ASCII name of the log file<br>The names stderr and stdout are treated specially and result in directing the log to those standard file descriptors. |  |

**Table 3 – dt\_init Parameters**

**Description**

The dt\_init function – the first API function called by a custom application—establishes the logging options and log name for the duration of the API library use. Usually this is the duration of the execution of the custom application, but you can use the [dt\\_shutdown](#) function to terminate use of the API library prior to termination of the custom application.

**Return Values**

dt\_init returns 1, indicating the API is initialized.

## dt\_lock\_print

### Prototype

```
void dt_lock_print(void)
```

### Parameters

None

### Description

The `dt_lock_print` function acquires the mutex used to single-thread print into the API's log file. Holding this lock across multiple calls to printing routines keeps all the lines in a file together with no lines interspersed from other threads.

## dt\_open

### Prototype

```
int dt_open(char *hp, int mode, int encap,
            int (*call_back)(void *usr_ptr, int fd),
            void *usr_ptr)
```

### Parameters

| Parameter             | Description   |   |
|-----------------------|---|---|
| <a href="#">hp</a>    | Pointer to an ASCII string denoting the host and port information for the connection<br><br>The value of this parameter varies depending upon the mode of the open. |   |
| <a href="#">mode</a>  | Option  | Description   |
|                       | DT_O_HOST   | Open the connection in <i>host</i> mode. This implies listening for an incoming connection from some remote host. This option is exclusive with the DT_O_CLIENT option. |
|                       | DT_O_CLIENT   | Open the connection in <i>client</i> mode. This implies actively connecting to a remote host. This option is exclusive with the DT_O_HOST option.                       |
| <a href="#">encap</a> | A mnemonic indicating the type of encapsulation to use for passing data via this connection   |   |

| Parameter | Description   |   |
|-----------|---|---|
| hlen_mode | Option  | Description   |
|           | HLEN_MODE_DEFAULT   | Use default defined value. Normally set to not include header size in the size field. |
|           | HLEN_MODE_INCLUDE_HSIZE   | Include header size in the size field.  |
|           | HLEN_MODE_EXCLUDE_HSIZE   | Do not include header size in the size field.   |
| call_back | Pointer to a routine called at a later time when the connection completes<br>Used for both incoming and outgoing connections. |   |
| usr_ptr   | Pointer passed to the callback routine  |   |

Table 4 – dt\_open Parameters

## Description

The `dt_open` function opens a socket-based connection to or from a remote or local host.

The `dt_open` function creates a thread, if one has not already been created, to monitor for incoming connections or a completed outgoing connection. When either of these events occurs, the thread calls the custom application's callback routine, passing it the `usr_ptr` and file descriptor for the opened data socket.

When a host mode connection setup completes, the listening thread continues to listen on the indicated port. As a result, there may be a number of thread instances invoking the callback routine with the same `usr_ptr` and different file descriptor values. Code the callback routine accordingly.

The callback routine is invoked from within the context of the listener or connection setup thread. It should either:

- Create a new thread/process to handle the newly established connection by using `clone` or `fork`.
- Or arrange to add the new file descriptor to a parent process's poll list or the equivalent

For incoming connections: Upon success (willingness to accept the connection), the callback routine returns 1. Upon failure it returns 0.

For outgoing connections: The callback routine is called only upon successful completion of a connection. If an outgoing connection fails to complete, the callback routine is not called and cleanup related to the failure is handled entirely by the outgoing connect completion thread. The custom application may set a time limit for how long to wait before assuming the connection failed to complete.

## Return Values

`dt_open` returns either 0 or the value `INVALID_SOCKET`.

`INVALID_SOCKET` does not necessarily indicate an error. If `errno` is set to `EWOULDBLOCK` or `EINPROGRESS`, `INVALID_SOCKET` means the socket is listening (host mode) or opening (client mode).

## hp and mode Parameters

The `hp` parameter points to an ASCII string that is interpreted differently depending upon the settings of the `mode` parameter:

| mode Parameter Value     | hp Parameter Interpretation  |
|--------------------------|--|
| <code>DT_O_HOST</code>   | <code>port</code> – The API uses the port number as the local port on which to listen for incoming TCP connections. The client must connect to this same port number on this same host to complete the TCP connection. For example: "9000"                                     |
| <code>DT_O_CLIENT</code> | <code>host:port</code> – <ul style="list-style-type: none"> <li>• <code>host</code> = host name of the remote host and can be a mnemonic or an IP address in dot notation.</li> <li>• <code>port</code> = port number to which to connect.</li> </ul> For example: "GPA1:9000" |

Table 5 – hp Parameter Interpretations of mode Parameter for the `dt_open` Function

## Encapsulation Mnemonics for `dt_open` Function:

| encap Parameter Value              | Description               |
|------------------------------------|---------------------------|
| <code>DT_ENCAP_LEN1</code>         | Count   Payload           |
| <code>DT_ENCAP_LEN2</code>         | Count   Payload           |
| <code>DT_ENCAP_LEN4</code>         | Count   Payload           |
| <code>DT_ENCAP_ATALLA</code>       | <   Payload   >           |
| <code>DT_ENCAP_ATALLA_OPT23</code> | <   Payload   >   0D   0A |
| <code>DT_ENCAP_BANCNET</code>      | Count   00   Payload      |

| encap Parameter Value | Description   |         |         |         |         |         |     |         |     |     |     |  |     |     |  |     |     |
|-----------------------|---|---------|---------|---------|---------|---------|-----|---------|-----|-----|-----|--|-----|-----|--|-----|-----|
| DT_ENCAP_BISYNC       | <p style="text-align: center;">Payload</p> <table border="1" style="margin: auto;"> <tr> <td>DLE</td> <td>STX</td> <td></td> <td>DLE</td> <td>DLE</td> <td></td> <td>DLE</td> <td>ETX</td> </tr> </table> <p style="text-align: center;">Payload</p> <table border="1" style="margin: auto;"> <tr> <td>DLE</td> <td>STB</td> <td></td> <td>DLE</td> <td>DLE</td> <td></td> <td>DLE</td> <td>ETB</td> </tr> </table> | DLE     | STX     |         | DLE     | DLE     |     | DLE     | ETX | DLE | STB |  | DLE | DLE |  | DLE | ETB |
| DLE                   | STX   |         | DLE     | DLE     |         | DLE     | ETX |         |     |     |     |  |     |     |  |     |     |
| DLE                   | STB   |         | DLE     | DLE     |         | DLE     | ETB |         |     |     |     |  |     |     |  |     |     |

**Table 6 – Encapsulation Mnemonics for dt\_open Function**

## dt\_printf

### Prototype

```
void dt_printf(char *fmt, ...)
```

### Parameters

| Parameter            | Description   |
|----------------------|---|
| fmt                  | Pointer to a character string with format information in the manner of the printf library routine |
| Remaining parameters | Values to be printed according to the format string   |

**Table 7 – dt\_printf Parameters**

### Description

The dt\_printf function prints a message into the API log file. The location of the log file is set by the [dt\\_init](#) function.

## dt\_rcv

### Prototype

```
int dt_rcv(SOCKET fd, int len, void *data, int *more)
```

## Parameters

| Parameter | Description  |
|-----------|--|
| fd        | File descriptor for the socket connection  |
| len       | Size of the custom application buffer  |
| data      | Pointer to the custom application buffer   |
| more      | Pointer to an integer that can hold the <i>more data indicator</i> that may accompany the received message<br>May be NULL. |

**Table 8 – dt\_recv Parameters**

## Description

The `dt_recv` function:

- Receives an encapsulated data message from the TCP socket.
- Deposits the data portion in the custom application's buffer.
- Returns its length.

When the custom application calls the `dt_recv` function, the function returns 0 if the entire message has not been received. Call the `dt_recv` function again when more data arrives, with the same parameters, to receive the entire message.

If the custom application's buffer is not large enough to hold the received message, the `dt_recv` function returns -1 and sets `errno` to `ENOBUFFS`.

**Note:** It is first necessary to call `poll` or the equivalent to ensure the file descriptor is read-ready.

The `more` pointer returns the *more data indicator* for encapsulation types using this indicator. If the custom application passes a NULL pointer to the `dt_recv` function, the `more` flag is not returned. If the `more` data indicator is non-zero upon return from the `dt_recv` function, regard the received message as one element of a longer message whose additional parts will be received via subsequent calls to the `dt_recv` function.

## Return Values

Upon success, `dt_recv` returns the length of the received data.

Upon failure, `dt_recv` returns a negative number with `errno` set to reflect the error condition. If `errno` is set to:

- `ECONNRESET` – The underlying socket has experienced an error and should be closed by the custom application.
- `EAGAIN` – The incoming message is discarded; the custom application should return to invoking `poll`.

- ENOBUFS – The custom application buffer is not large enough for the incoming data.

## dt\_reuseaddr

### Prototype

```
void dt_reuseaddr(void);
```

### Parameters

None

### Description

The `dt_reuseaddr` function enables setting of the `SO_REUSEADDR` socket option on listening sockets. After calling this function, any [dt\\_open](#) calls that specify a host mode connection result in enabling the `SO_REUSEADDR` socket option on the listening socket. This is provided primarily for server development purposes to prevent waiting for the `TIME_WAIT` time to expire before restarting the server.

### Notes:

- If you enable this option, it is possible to receive garbage on the listener from any connections that were active when the server was shut down.
- If the option does not appear to work and you are using Linux, be aware this socket option is buggy in many Linux kernels.

### Return Values

None

## dt\_send

### Prototype

```
int dt_send(SOCKET fd, int len, void *data, int more)
```

### Parameters

| Parameter | Description  |
|-----------|--|
| fd        | File descriptor for the socket connection                |
| len       | Number of bytes of data to send                          |
| data      | Pointer to the bytes of data to be sent after the header |
| more      | Set the <i>more data indicator</i> if appropriate        |

Table 9 – dt\_send Parameters

### Description

The `dt_send` function sends encapsulated data on the indicated socket. The `len` parameter identifies the length of the payload data. The API adds the encapsulation information prior to sending the message on the socket.

If the API cannot send the entire message on the socket because of flow control constraints, the `dt_send` function returns `-1` and sets `errno` to either `EAGAIN`, `EINTR` or `EWOULDBLOCK`. In this case, simply call the `dt_send` function with the same parameters after `poll` indicates that the socket is write-ready again.

### Return Values

Upon success, `dt_send` returns the value of the `len` parameter to indicate all bytes have been sent.

Upon failure, `dt_send` returns a negative number with `errno` set to reflect the error condition. If `errno` is set to:

- `ECONNRESET` – The underlying socket has experienced an error and should be closed by the custom application.
- `EAGAIN` – The API cannot send the entire message on the socket because of flow control constraints.
- `EINTR` – The API cannot send the entire message on the socket because of flow control constraints.
- `EWOULDBLOCK` – The API cannot send the entire message on the socket because of flow control constraints.

### dt\_set\_log\_size

#### Prototype

```
void dt_set_log_size(int wrap_point, int max_size)
```

#### Parameters

| Parameter  | Description  |  |
|------------|--------------|--|
| wrap_point | <b>Value</b> | <b>Description</b>                               |
|            | -2           | Do not change the wrap point.                    |
|            | -1           | Set the wrap point to the current position.      |
|            | 0            | Set the wrap point to the beginning of the file. |
|            | >0           | Set the wrap point to this byte offset.          |
| max_size   | <b>Value</b> | <b>Description</b>                               |
|            | 0            | Log can grow without bound.                      |
|            | >0           | Log size in bytes before wrap-around.            |

Table 10 – `dt_set_log_size` Parameters

#### Description

The `dt_set_log_size` function sets the boundaries of the log file. You can set the log file to grow without bound or to wrap when it reaches a size you define.

The most common usage: Write some initialization information into the log and then use `dt_set_log_size(-1, max_size)` to limit log file size and set the wrap point just beyond the initialization information.

## **dt\_shutdown**

### **Prototype**

```
void dt_shutdown(void)
```

### **Parameters**

None

### **Description**

The `dt_shutdown` function terminates all API operations. It kills any internal threads started by the API and closes the log file unless the log file is set to `stderr` or `stdout`.

## **dt\_unlock\_print**

### **Prototype**

```
void dt_unlock_print(void)
```

### **Parameters**

None.

### **Description**

The `dt_unlock_print` function releases the mutex used to single-thread print into the API's log file.

## Gcom Protocol Converter Daemon

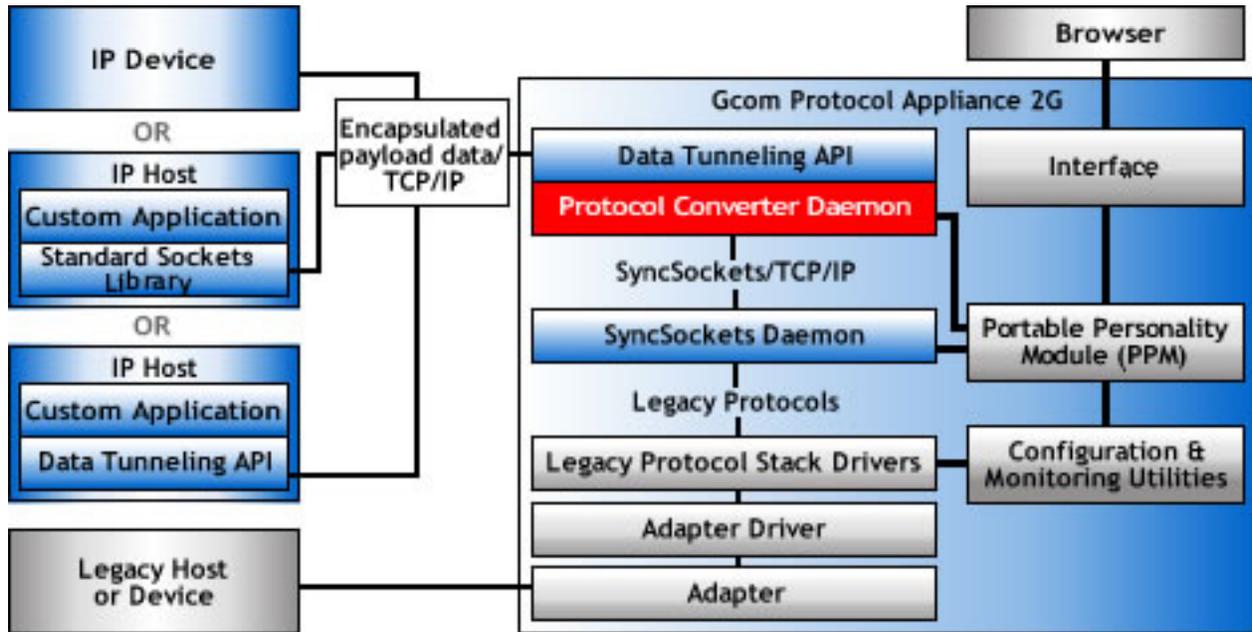

Figure 3 – Gcom Protocol Converter Daemon

The Protocol Converter Daemon is a Gcom-proprietary, stand-alone application-level program that converts legacy protocol data streams from Gcom’s SyncSockets protocol to encapsulated payload data over TCP/IP.

The Protocol Converter Daemon uses:

| Gcom API...        | To...   |
|--------------------|---|
| SyncSockets API    | <ul style="list-style-type: none"> <li>Manage SyncSockets (socket connections) to legacy protocol connections.</li> <li>Exchange data with the SyncSockets Daemon, an intermediary to the legacy protocol connections.</li> </ul> |
| Data Tunneling API | <ul style="list-style-type: none"> <li>Manage TCP connections to the custom application or IP device.</li> <li>Perform encapsulation on the payload data.</li> </ul>  |

Table 11 – Gcom Protocol Daemon and Gcom APIs

A single Protocol Converter Daemon can:

- Manage multiple connections – even if those connections are to different legacy protocols.
- Act as a client or a server (listening) for TCP/IP connections to/from the custom application or IP device on a connection-by-connection basis.

- Manage SyncSockets connections to the SyncSockets Daemon on a per-connection basis to initiate legacy connections or to wait for the legacy host/device to initiate connections.

You may run:

- Multiple instances of the Protocol Converter Daemon, each with its own configuration file/command line that identifies a set of non-interfering encapsulated TCP and SyncSockets connections
- Routes for different legacy protocol connections through a single instance of the Protocol Converter Daemon (because the Protocol Converter Daemon is not sensitive to the type of legacy protocol)
- Multiple custom applications with no restrictions on Protocol Converter Daemon usage

## Gcom\_pcd

Gcom\_pcd – the Protocol Converter Daemon program – accepts the following command line options and arguments:

| Option & Argument     | Description   | Optional/Required  |
|-----------------------|---|--|
| -B                    | Run Gcom_pcd in the background and detach from its controlling tty.   | Optional   |
| -c <i>filename</i>    | Name of the configuration file read by Gcom_pcd   | Required if using a <a href="#">configuration file</a> to configure Gcom_pcd |
| -d <i>mask</i>        | Mask of debug bits  | Optional   |
| -e [+ -] <i>encap</i> | Default <a href="#">encapsulation</a><br>You may have multiple occurrences of this option on a single command line.   | Required if using a <a href="#">command line</a> to configure Gcom_pcd       |
| -f <i>filename</i>    | Log file name   | Optional   |
| -h                    | Print option list   | Optional   |
| -i #1,#2,#3,#4        | Keep alive settings in seconds. #1 is required. #2 - #4 are optional. Zero = infinite.<br><br>#1 – Number of seconds of idle time before link is dropped.<br><br>#2 – Send keep alive after #2 seconds.<br><br>#3 – Number of seconds between keep alive pulse.<br><br>#4 – Number of failed keep alive responses before considering link down. | Optional   |
| -n <i>number</i>      | Maximum number of connections<br><br>Default: 100   | Optional   |
| -p <i>msecs</i>       | Poll timeout in milliseconds  | Optional   |
| -q <i>file-size</i>   | Log file size in kilobytes  | Optional   |
| -R <i>secs</i>        | Number of seconds to wait before reconnecting with the SSD (Default is 30 sec.)   | Optional   |
| -r <i>route-spec</i>  | Define a connection route through Gcom_pcd.<br>You may have multiple occurrences of this option on a single command line.   | Required if using a <a href="#">command line</a> to configure Gcom_pcd       |
| -t <i>secs</i>        | Connection setup time   | Optional   |
| -v                    | Print version information   | Optional   |

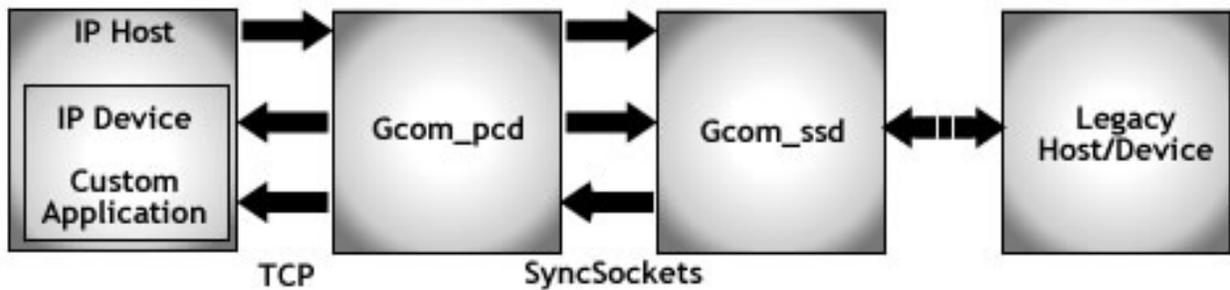

**Table 12 – All Gcom\_pcd Command Line Options and Arguments**

**Notes:**

- Recommended method for configuring Gcom\_pcd: [Configuration file](#).
- Gcom’s current browser-based interface to the Gcom\_pcd does not support creation of a configuration file; you must create the configuration file yourself.
- Do NOT mix the -c argument with the -r /-e arguments on a single command line.

**Connection Setup and Cloned Connections**

The Protocol Converter Daemon tries to synchronize connection setup between the TCP connection and the legacy connection when possible in the following ways:

**Figure 4 – Connection Initiation**

| TCP Connection | Legacy Connection | Gcom_pcd Synchronization Steps  |
|----------------|-------------------|---|
| Listening      | Outgoing          | <ol style="list-style-type: none"> <li>1. Issue <code>listen</code> on a socket.</li> <li>2. When a connection arrives, open a SyncSockets connection to Gcom_ssd (the SyncSockets Daemon) and issue an <code>SS_OP_CONN_REQ</code>.</li> <li>3. Receive an <code>DT_OP_CONN_CONF</code> from Gcom_ssd.</li> <li>4. Issue an <code>accept</code> on the socket.</li> </ol>  |
| Outgoing       | Outgoing          | <ol style="list-style-type: none"> <li>1. Open the SyncSockets connection and issue an <code>SS_OP_CONN_REQ</code> to Gcom_ssd.</li> <li>2. Open the TCP socket and issue a <code>connect</code>.</li> <li>3. Block data flow until both connections are complete.</li> </ol> <p>The SyncSockets connection is complete upon receipt of an <code>DT_OP_CONN_CONF</code>.</p> <p>The TCP socket connection is complete upon receipt of a poll event.</p> |

| TCP Connection | Legacy Connection | Gcom_pcd Synchronization Steps  |
|----------------|-------------------|---|
| Outgoing       | Listening         | <ol style="list-style-type: none"> <li>1. Open a SyncSockets connection and send an SS_OP_LISTEN to Gcom_ssd.</li> <li>2. Receive an SS_OP_CONN_REQ from Gcom_ssd.</li> <li>3. Issue a connect on the TCP connection.</li> <li>4. If the legacy connection is X.25, open a new SyncSockets connection to Gcom_ssd and send an SS_OP_LISTEN.</li> <li>5. When the TCP connection completes, send an SS_OP_CONN_CONF to Gcom_ssd on the original SyncSockets connection.</li> </ol> |

**Table 13 – Connection Synchronization**

You may use a single connection definition to produce multiple actual connections.

All TCP connections can be cloned connections. Once you define an IP address and port number, you can open multiple actual connections to that destination. Similarly, if you are listening on a port number, you can receive multiple incoming connections to that port.

As for the different legacy protocols handled by the SyncSockets Daemon, only X.25 Switched Virtual Circuits (SVCs) can be cloned connections:

- Once you configure a route between an X.25 SVC and a TCP connection, this route can represent multiple actual connections. Keep this in mind when you set parameters for the maximum number of routes in the Protocol Converter Daemon.
- If you define a listening X.25 SVC connection paired with an outgoing TCP connection, the Protocol Converter Daemon keeps a listening SyncSockets connection in place to the SyncSockets Daemon. Thus, multiple incoming X.25 connections to the Protocol Converter Daemon trigger multiple outbound TCP connections.
- If you configure a listening TCP connection paired with an outgoing X.25 SVC connection, the Protocol Converter Daemon holds the listening socket open so that additional TCP connections can arrive and trigger outgoing SyncSocket connections.

## Configuration Using the Gcom\_pcd Configuration File

Use a Gcom\_pcd configuration file to tell a Protocol Converter Daemon how to:

- Handle its log file.
- Handle its poll list.
- Set up connections between the custom application and the SyncSockets Daemon.
- Handle the encapsulations on the TCP connections to the custom application.

Each section of a Gcom\_pcd configuration file consists of a left-justified label followed by indented lines containing parameters. The following table offers a small example, with annotations, that illustrates the general form of the file.

| Label/Parameter  | Description   |
|--|---|
| <pre>global:   max_routes = 100</pre>  | <p>The first label is always <code>global</code>, with parameters that define settings for Gcom_pcd as a whole.</p> <p><code>max_routes</code> defines the maximum number of routes that can be:</p> <ul style="list-style-type: none"> <li>• Defined in the rest of the file</li> <li>• Active at any one time, which can be larger than the number defined in the file</li> </ul>   |
| <pre>route.1:   left  = "tcp_listen"   right = "sna_connect"   encap = "cisco-rbp"</pre> | <p>Gcom_pcd scans the file for entries named <code>route.1</code>, <code>route.2</code>, up to <code>max_routes</code>. For any entries of that form found in the file, Gcom_pcd takes the descriptive information and adds it to its routing table.</p> <p>This sample route is:</p> <ul style="list-style-type: none"> <li>• A listening TCP connection using the Cisco RBP encapsulation...</li> <li>• Connected to an outgoing SNA connection.</li> </ul> <p>The connection definitions appear later in the file.</p> |
| <pre>tcp_listen:   host-port = "8001"   is_listen = 1   conn_name = ""</pre>             | <p>Left connection name</p> <p>This sample connection is a TCP connection listening on port 8001.</p>   |

| Label/Parameter   | Description  |
|---|--|
| <u>sna_connect:</u><br>host-port = "localhost:8000"<br>is_listen = 0<br>conn_name = "sna" | Right connection name<br>This sample connection goes to a SyncSockets Daemon on the local machine.<br>Gcom_pcd sends an SS_OP_CONN_REQ to the SyncSockets connection named "sna" to establish this connection. |

Table 14 – Gcom\_pcd Configuration File Label and Parameter Excerpt

## Gcom\_pcd Configuration File Global Parameters

The following table shows the available parameters for the configuration file [global:](#) entry.

| Parameter         | Type   | Description  |
|-------------------|--------|--|
| connect_timeout   | Number | Maximum time in seconds allowed for: <ul style="list-style-type: none"> <li>• A deferred TCP connection to complete</li> <li>• Or for an SS_OP_CONN_CONF to be returned from Gcom_ssd (the SyncSockets Daemon) in response to Gcom_pcd sending an SS_OP_CONN_REQ.</li> </ul> Default: 10 |
| max_routes        | Number | Maximum number of routes that can be serviced simultaneously<br>The scanning for "route.n:" labels in the configuration file runs from 1 to this value.<br>Default: 100  |
| max_log_size      | Number | Log file size in kilobytes<br>Set to 0 for unlimited log file size.<br>Default: 8000 (which yields an 8-MB circular log file)  |
| poll_timeout      | Number | Timeout parameter to use when calling poll<br>Default: 1000<br>Recommendation: Do not change default value.  |
| reconnect_timeout | Number | Maximum time in seconds at which connection reestablishment occurs.<br><b>NOTE:</b> Must be greater than or equal to <a href="#">connect_timeout</a> .<br>Default: 30  |

| Parameter         | Type   | Description  |  |
|-------------------|--------|--|--|
| reuse_addr        | Number | Value  | Description  |
|                   |        | 1<br>(Default)   | Set the SO_REUSEADDR socket option on listening TCP connections to prevent the listening socket from entering the TIME_WAIT state when Gcom_pcd is terminated. |
|                   |        | 0  | Do <b>NOT</b> prevent the listening socket from entering the TIME_WAIT state.  |
| run_in_background | Number | Set to non-zero to cause Gcom_pcd to run in background mode. |  |

Table 15 – Gcom\_pcd Configuration File Global Parameters

### Gcom\_pcd Configuration File Route Parameters

The following table shows the available parameters for each configuration file entry of the form [route.n](#):

| Parameter             | Type  | Description   |  |
|-----------------------|---|---|--|
| left                  | String  | The name of the connection definition for the left connection of the route<br><br>This name must appear elsewhere in the configuration file as a label (left justified and followed by a colon character).  |  |
| right                 | String  | The name of the connection definition for the right connection of the route<br><br>This name must appear elsewhere in the configuration file as a label (left justified and followed by a colon character). |  |
| <a href="#">encap</a> | String  | A mnemonic indicating the type of encapsulation type to apply to the TCP connection.  |  |
| hlen_mode             | Number  | Inclusion of header in encapsulation length field   |  |
|                       |   | Value   | Description                                |
|                       |   | 0   | Use whatever protocol specification says.  |
|                       |   | 1   | Force header to be included in byte count. |
| 2                     | Force header to <b>NOT</b> be included in byte count. |   |  |

Table 16 – Gcom\_pcd Configuration File Route Parameters

## Gcom\_pcd Configuration File Connection Parameters

The following table shows the available parameters for each `left` and `right` connection name referenced in a `route.n:` entry.

| Parameter              | Type   | Description  |
|------------------------|--------|--|
| <code>host-port</code> | String | Format: " <code>host:port</code> "<br><b>For a listening TCP connection:</b> <ul style="list-style-type: none"> <li><code>host</code> = Host name or dotted notation IP address of sending IP host</li> <li><code>port</code> = IP port number on which to listen</li> </ul> <b>Note:</b> If <code>host = any</code> – Listen for an incoming connection from any IP host<br><b>For an outgoing TCP connection:</b> <ul style="list-style-type: none"> <li><code>host</code> = Host name or dotted notation IP address of target host</li> <li><code>port</code> = Target host's port number</li> </ul> <b>For a legacy connection:</b> <ul style="list-style-type: none"> <li>Host name and port number of the <code>Gcom_ssd</code> (SyncSockets Daemon) controlling the legacy connection identified in <a href="#">conn_name</a></li> <li>Usually = "<code>localhost:8000</code>"</li> </ul> |
| <code>is_listen</code> | Number | Set to 1 for a listening connection.<br>Default: 0   |
| <code>conn_name</code> | String | <b>For a TCP connection:</b> Empty string ""<br><b>For a legacy connection:</b> Name of the connection to which <code>Gcom_pcd</code> directs an <code>SS_OP_CONN_REQ</code> or <code>SS_OP_LISTEN</code> message  |

**Table 17 – Gcom\_pcd Configuration File Connection Parameters**

## Configuration Using the Gcom\_pcd Command Line

The following command line options are required if you use the command line to configure Gcom\_pcd:

| Option & Argument     | Description   |
|-----------------------|---|
| -e [+ -] <i>encap</i> | Default <a href="#">encapsulation</a><br>You may have multiple occurrences of this option on a single command line.       |
| -r <i>route-spec</i>  | Define a connection route through Gcom_pcd.<br>You may have multiple occurrences of this option on a single command line. |

Table 18 – Gcom\_pcd -r and -e Command Line Options and Arguments

### Gcom\_pcd -r Command Line Option

Use the -r option on a Gcom\_pcd command line to tell a Protocol Converter Daemon how to:

- Set up connections between the custom application and the SyncSockets Daemon.
- Handle the encapsulations on the TCP connections to the custom application.

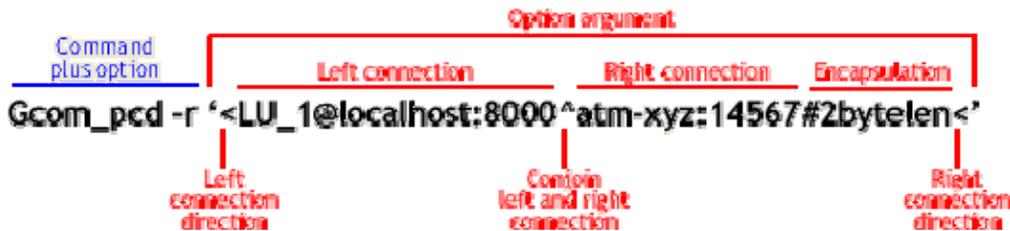

Figure 5 – Sample Gcom\_pcd -r Command Line

| Component                   | Purpose  |
|-----------------------------|--|
| Command line plus -r option | Configure a data connection route through a Protocol Converter Daemon.<br><b>Note:</b> You can configure multiple data routes on a single command by coding multiple occurrences of the -r option. |

| Component                 | Purpose   |
|---------------------------|---|
| Option argument           | <ul style="list-style-type: none"> <li>• Identify a TCP connection – IP address, port number, connection direction, and encapsulation technique.</li> <li>• Identify a legacy connection – Name of the connection defined in the Gcom_ssd (SyncSockets Daemon) Configuration file, and connection direction.</li> <li>• Bind the two connections together in a data route through a Protocol Converter Daemon.</li> </ul> <p><b>Recommendation:</b> Enclose the argument in single quote/apostrophe characters to prevent shell interpretation of the characters within the argument.</p>   |
| Left and right connection | <p>Left connection – Identifies TCP connection parameters or a SyncSockets connection name.</p> <p>Right connection – Identifies TCP connection parameters or a SyncSockets connection name.</p> <p>It doesn't matter if you use left to identify a TCP or SyncSockets connection, or right to identify a TCP or SyncSockets connection, as long as you have one of each connection type.</p> <p>Identify a TCP connection in the following manner: <i>host:port</i></p> <p>where:</p> <ul style="list-style-type: none"> <li>• <i>host</i> = Host name or a dotted notation IP address</li> <li>• <i>port</i> = IP port number</li> </ul> <p>Identify a SyncSockets connection in the following manner: <i>conn-name@host:port</i></p> <p>where:</p> <ul style="list-style-type: none"> <li>• <i>host:port</i> = Gcom_ssd location</li> <li>• <i>conn-name</i> = Name of the legacy connection to target within that Gcom_ssd</li> </ul> |

| Component            | Purpose   |
|----------------------|---|
| Connection direction | <p>Identify if Gcom_pcd should actively connect or passively listen. In the case of a TCP connection, this means Gcom_pcd uses either the <code>socket connect</code> routine or the <code>listen</code> routine. In the case of a SyncSockets connection, this means Gcom_pcd sends either an <code>SS_OP_CONN_REQ</code> or an <code>SS_OP_LISTEN</code> on the SyncSockets connection.</p> <p>Use the &lt; or &gt; character to identify connection direction for both the left and right connections.</p> <ul style="list-style-type: none"> <li>• Actively connect = An arrow pointing away from a connection definition</li> <li>• Passively listen = An arrow pointing toward a connection definition</li> </ul> <p>In the <a href="#">sample</a> above:</p> <ul style="list-style-type: none"> <li>• The TCP connection (<code>atm_xyz:14567</code>) passively listens.</li> <li>• The legacy connection (<code>LU_1@loclahost:8000</code>) actively connects.</li> </ul> |
| Encapsulation        | <p>Optional – Identifies a specific encapsulation for this data route (and overrides a default encapsulation identified in the <code>-e</code> command line option)</p> <p>All encapsulations use some form of header preceding the message payload data that includes a byte count within the header except as noted in <a href="#">Header Byte Count Exceptions</a>.</p> <p>Encapsulation notation formats for the <code>-r</code> option:</p> <ul style="list-style-type: none"> <li>• <code>#<a href="#">encap</a></code> – Include/exclude byte count of the header itself in/from the header length depending upon the protocol specification.</li> <li>• <code>#+<a href="#">encap</a></code> – Always include byte count of the header itself in the header length.</li> <li>• <code>#-<a href="#">encap</a></code> – Always exclude byte count of the header itself from the header length.</li> </ul>   |

Table 19 – Gcom\_pcd -r Command Line Components

## **Gcom\_pcd -e Command Line Option**

Use the `-e` option on a `Gcom_pcd` command line to tell a Protocol Converter Daemon how to handle the encapsulations on the TCP connections to the custom application.

All encapsulations use some form of header preceding the message payload data that includes a byte count within the header except as noted in [Header Byte Count Exceptions](#).

Encapsulation notation formats for the `-e` option:

- `encap` – Include/exclude byte count of the header itself in/from the header length depending upon the protocol specification.
- `+encap` – Always include byte count of the header itself in the header length.
- `-encap` – Always exclude byte count of the header itself from the header length.

You can use `-e` option multiple times on a single command line, in which case each `-e` option encapsulation applies to all `-r` options (that lack encapsulation information) to the right of the `-e` option until another `-e` option is encountered.

## **Header Byte Count Exceptions**

- The Bisync and ETX encapsulations use bytes at the beginning and the end of each message instead a prefix containing a byte count.
- The Atalla encapsulations communicate with the HP Atalla encryption device and do not actually add and strip the Atalla prefix and suffix characters. These characters are assumed to be present in the legacy protocol data stream and are passed through transparently. Any bytes in the legacy data stream outside the Atalla prefix/suffix are discarded.

### Encapsulation Mnemonics for Gcom\_pcd

| Mnemonic     | Description   |     |     |     |     |     |     |     |     |     |     |  |     |     |  |     |     |
|--------------|---|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|--|-----|-----|--|-----|-----|
| 1bytelen     | Count Payload   |     |     |     |     |     |     |     |     |     |     |  |     |     |  |     |     |
| 2bytelen     | Count Payload   |     |     |     |     |     |     |     |     |     |     |  |     |     |  |     |     |
| 4bytelen     | Count Payload   |     |     |     |     |     |     |     |     |     |     |  |     |     |  |     |     |
| atalla       | < Payload >   |     |     |     |     |     |     |     |     |     |     |  |     |     |  |     |     |
